Eye Dosimetry with VARSKIN?

- VARSKIN originally intended for estimating shallow dose from skin contamination to show compliance with US Regulation 10 CFR 20.1201
 - 10 CFR 20 limit (1991) of 150 mSv/yr from ICRP 26
- ICRP 118 (2012) guidance for the dose limit to the lens
 - 20 mSv/yr averaged over 5 consecutive years, not to exceed 50 mSv in any single year
 - change indicated by higher incidence at lower dose over longer follow-up times
 - data imply that the “injury ... is caused by single-hit irreparable-type events”
- Some users have turned to VARSKIN for eye dosimetry of beta emitters
- In its current state (V6.1), how well does VARSKIN estimate lens dose?

Eye Dosimetry

- We compared VARSKIN 6.1 to Monte Carlo simulation (MCNP6)
- Using a simplified eye model with cornea, lens, and surrounding tissue all assumed to be of unit density
 - to be closest to VARSKIN assumptions
- Point sources located along centerline from contact to 20 cm
- Dose estimated per incident electron
 - to normalize for geometry
 - cross-sectional area of 1 cm^2 with $20 \text{ }\mu\text{m}$ thickness, centered at a depth of 3 mm

Source on Contact

VARSKIN underestimates by at least 10%

Dose to the Lens

Ratio of VARSKIN to MCNP Dose

- All results are normalized for geometry to show dose per electron incident on the eyeball
- Normalized VARSKIN results are consistent, whereas MCNP results are indicative of different patterns of energy loss during electron transport

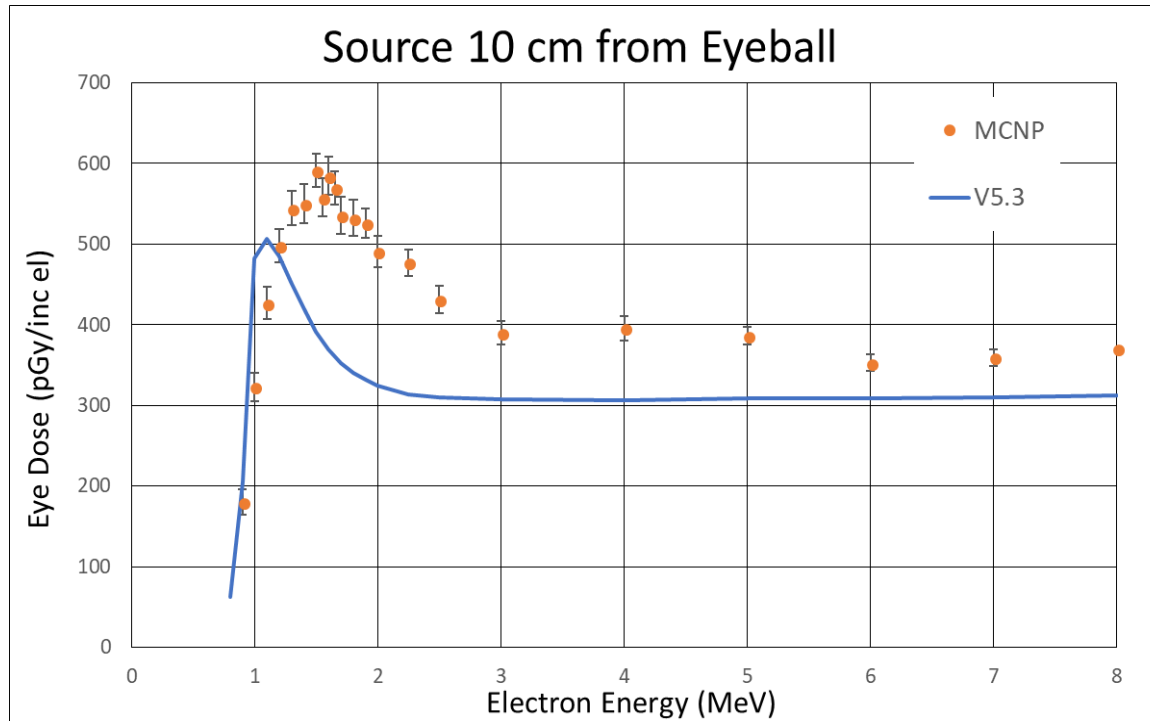

5
*

2 1
* *

- MCNP accounts for scattered paths; VARSKIN uses CSDA assumption

Modeling the Eyelid

- Eyelid assumed to be 0.3 mm thick
- Two scenarios:
 - on the exterior of the closed eyelid
 - on the interior of the closed eyelid
- VARSKIN cannot model a source under a closed eyelid
- The best we can do is to alter the backscatter material, either air or water

Conclusion/Recommendations

- How to accurately predict eye dose?
 - modification to the models for energy-loss in air and cover materials, and the ability to model greater separation distances
- While accurate for shallow depth, VARSKIN in its current iteration underpredicts most scenarios of eye dosimetry
- Monte Carlo considers bremsstrahlung and tortuous path
- VARSKIN considers energy conservation and CSDA range
- On contact, both show upturn at high energy; both show similar shape; VARSKIN underestimates MCNP by 10%
- With air gap, VARSKIN demonstrates no energy shift
- VARSKIN structure provides a good foundation for eye dosimetry implementation, but careful modeling is necessary
