**EYE DOSE**

RENAISSANCE CODE DEVELOPMENT  
Colby Mangini, PhD. CHP

# OUTLINE

- Technical Basis
  - Using VARSKIN
- Eye Dosimetry
  - Photon Dose
  - Electron Dose
- V&V
- Examples

## REGULATORY BASIS FOR EYEDOSE

- In the United States from 10 CFR 20.1201 (1991):
  - 150 mSv/yr
- Internationally from ICRP 118:
  - 20 mSv/yr averaged over 5 consecutive years, not to exceed 50 mSv in any single year
- Many nations adopted the new ICRP recommendations, causing a renewed interest in eye dosimetry
  - Some VARSKIN (NRC approved code) users wanted to use code to estimate eye dose

## SENSITIVITY BY STRUCTURE

- In order of decreasing sensitivity (Rohrschneider, 19)
  - Lens
  - Conjunctiva
  - Cornea
  - Uvea
  - Retina
  - Optic Nerve
- Assumption: Protect the lens and protect the eye

## PRIOR TO EYEDOSE

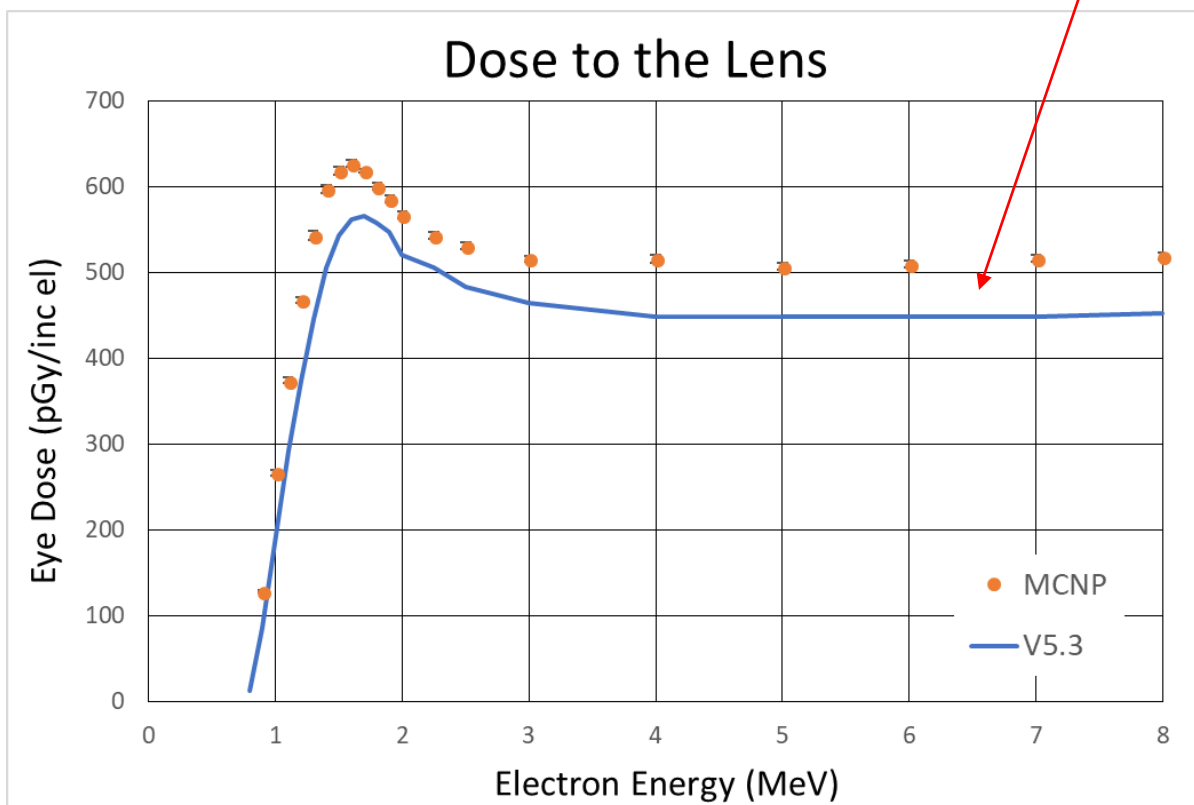

- We compared VARSKIN 5.3 to Monte Carlo simulation (MCNP6)
- Using a simplified eye model with cornea, lens, and surrounding tissue all assumed to be of unit density
  - to be closest to VARSKIN assumptions
- Point sources located along centerline from contact to 20 cm
- Dose estimated per incident electron
  - to normalize for geometry
  - cross-sectional area of  $1 \text{ cm}^2$  with 20 mm thickness, centered at a depth of 3 mm

# SOURCE ON CONTACT

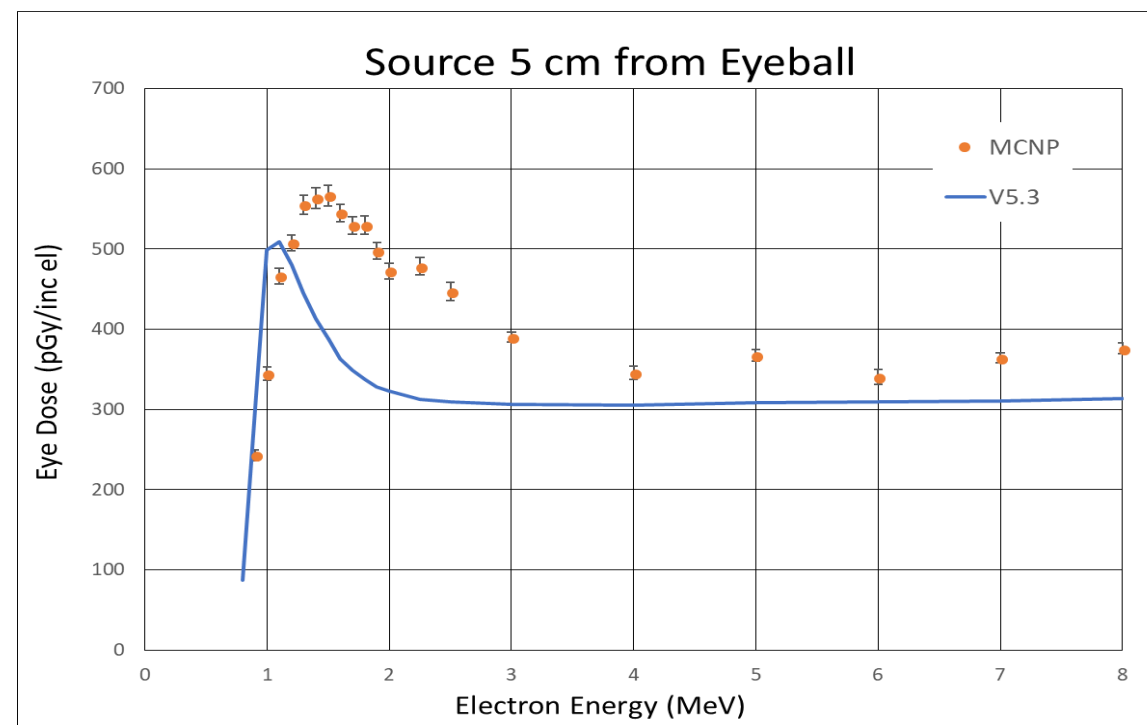

VARSKIN underestimates by at least 10%

# WITH AIR GAP

10

# 1 CM GAP WITH PLASTIC

Source 1 cm from Eyeball

Source 1 cm from Eyeball (w/ 0.3 cm Plastic)

## 2 CM GAP WITH PLASTIC

Source 2 cm from Eyeball

Source 2 cm from Eyeball (w/ 0.3 cm Plastic)

# MONTE CARLO METHODS

- “Random walk” physics simulator
  - Average behavior of the typical particle
- Gold standard in particle transport
  - MCNP6, EGS, GEANT, etc.
- Pros
  - Customizable geometries
  - Multiple particle transport
  - Multiple energy
- Cons
  - Time intensive
  - Steep learning curve
  - Output files difficult to interpret

## EYEDOSE MODEL

- A set of deterministic equations were developed from a vast array of probabilistic simulations to estimate radiation dose to the lens of the eye
- The equations used in EyeDose were developed through Monte Carlo simulations of monoenergetic radioactive sources placed at varying distances from a stylized eye model
- Account for particle type, energy, source emission rate, and protective eyewear and are valid for:
  - electron energies ranging from 100 keV to 11 MeV
  - photon energies ranging from 7 keV to 11 MeV
  - distances from 0 to 20 meters.
- Additionally, sources emitting particles over an energy spectrum, such as beta sources, are incorporated into this new dosimetry model using both ICRP 38 and 107 data
- The source is assumed to be an infinitely small, isotropic point source located on the geometric axis of the eye
- The target volume is taken to be the entire lens

## EYE GEOMETRY

- The source in EyeDose is modeled as an infinitely small, monoenergetic, isotropic point source of energy  $E$
- The source is located on the geometric axis of the eye and the distance between the surface of the eyeball and the source is labeled  $r$
- The target volume is taken to be the entire lens

# PHOTON DOSIMETRY

- The development of the photon model begins with the uncollided fluence equation:

$$\Phi^0(r) = \frac{S_0}{4\pi r^2}$$

- Fundamental equation for absorbed dose to a point in space at some distance  $r$  from an isotropic source of photons:

$$D^0(r, E) = E \Phi^0 \frac{\mu_{en}}{\rho} B e^{-\mu r}$$

## PHOTON DOSIMETRY

- The lens, however, is a complex volume and not a single point
- The probabilistic modeling software MCNP6 was used to determine dose to the human lens over a range of photon energies after passing through, and scattering in, air and the cornea
- The resulting function for determining lens dose from photons of energy  $E$  emanating from an isotropic source at distance  $r$ , is

$$D_p(r, E) = \frac{\exp(-\mu r)}{tr^2 + ur + v} \quad \left(\frac{\mu}{\rho}\right)_{\text{air}} = \frac{\alpha_0 + \sum_{i=1}^6 \alpha_i \ln^i E}{1 + \sum_{i=1}^6 \beta_i \ln^i E},$$

- The parameters  $t$ ,  $u$ , and  $v$  describe the overall shape of the curve and  $\mu$  is the mass attenuation coefficient in air

# PHOTON DOSIMETRY

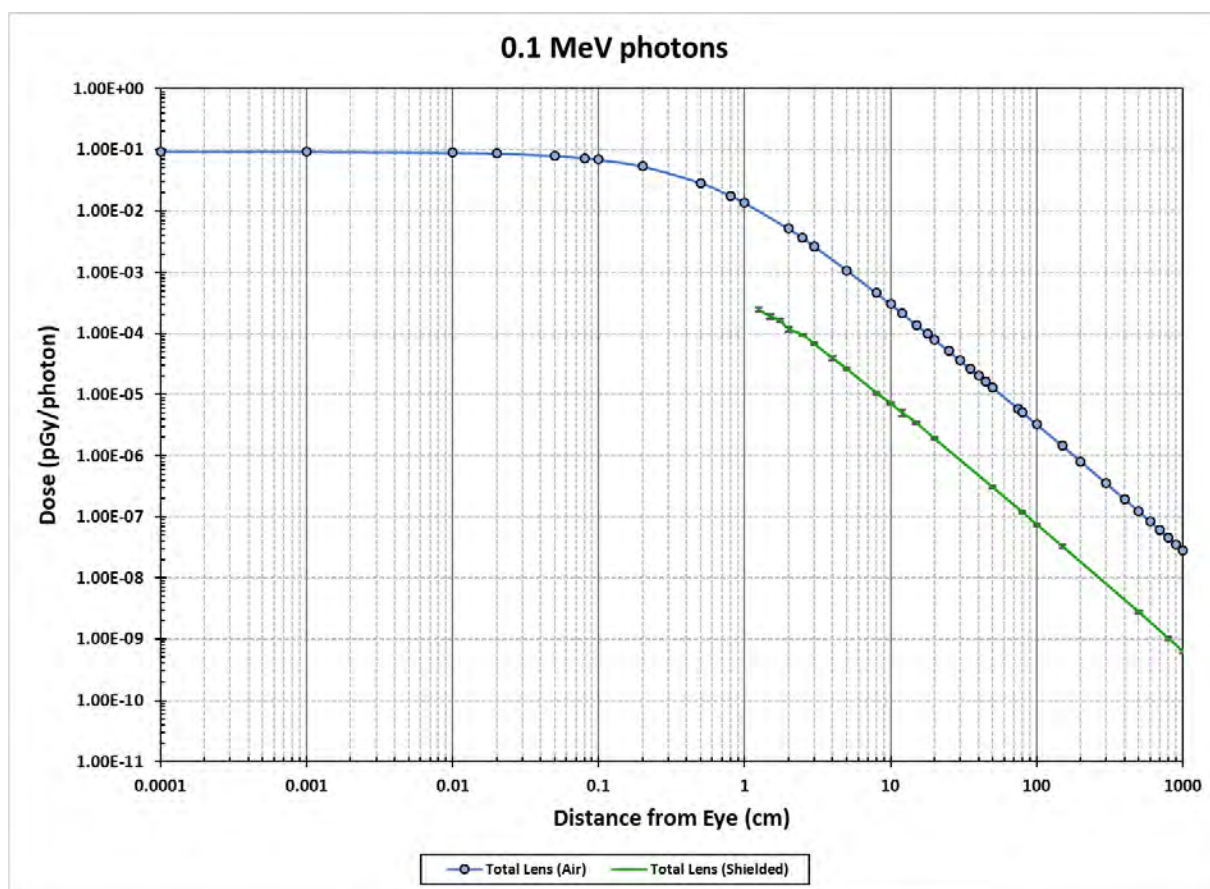

$$t = \exp \left[ \frac{\alpha_0 + \sum_{i=1}^5 \alpha_i \ln^i E}{1 + \sum_{i=1}^8 \beta_i \ln^i E} \right]$$

$$u = \exp \left[ \frac{\alpha_0 + \sum_{i=1}^9 \alpha_i \ln^i E}{1 + \sum_{i=1}^7 \beta_i \ln^i E} \right]$$

$$v = \exp \left[ \frac{\alpha_0 + \sum_{i=1}^9 \alpha_i \ln^i E}{1 + \sum_{i=1}^6 \beta_i \ln^i E} \right]$$

# PHOTON DOSIMETRY

## PROTECTIVE GLASSES

- The shielding used in the model is based on Spackman's "classic" style eyewear
- Adding the lens thickness of 2 mm places its anterior face 1.25 cm from the cornea's surface

# PROTECTIVE GLASSES

## PROTECTIVE GLASSES

- The concept of the *buildup factor* is extremely useful when estimating the dose after shielding has been introduced,
- Since the buildup factor is the ratio of total fluence to the primary fluence, total fluence can be expressed mathematically as:

$$\Phi(r) = B(r)\Phi^0(r)$$

- where  $\Phi(r)$  is the total fluence at point  $r$ ,  $\Phi^0(r)$  is the primary fluence at  $r$ , and the buildup factor is  $B(r)$
- Combining this concept with the equation for dose written as  $D=\Phi E(\mu_{ab}/\rho)$ , shows that the dose rate at a given point is related to the fluence at that point, and so one may write:

$$D_{\text{sh}}(r, E) = f(D_{\text{unsh}}(x, E)).$$

# ELECTRON DOSIMETRY

- Understanding the electron model in both shielded and unshielded circumstances first requires the analysis of the unshielded electron model in a vacuum
- Because the bremsstrahlung plays a significant role in electron dosimetry, it must be considered

## ELECTRON DOSIMETRY

- This new path opens at around  $r = 0.3$  cm. The electron rays radiating from the source can be considered parallel at about 10 cm, at which point both the bremsstrahlung and direct contribution obey the inverse square law.

# ELECTRON DOSIMETRY

## Absorbed Dose from 1 MeV electrons

## Absorbed Dose from 3 MeV electrons

## ELECTRON DOSIMETRY

- An empirical model that fits the MCNP probabilistic data for dose due to electron source, bremsstrahlung, and scattered contributions is

$$D_{\text{e,vac}}(r, E) = \frac{\mathcal{B}^{-}(q, s)}{ar^2 + br + c\sqrt{r} + d} + \frac{\mathcal{B}^{+}(q, s)}{tr^2 + ur + v}.$$

- The parameters  $a$ ,  $b$ ,  $c$ ,  $d$ ,  $t$ ,  $u$ , and  $v$  are all energy dependent shaping parameters and the functions  $\mathcal{B}^{+}$  and  $\mathcal{B}^{-}$  are modified hyperbolic tangent functions

# ELECTRON DOSIMETRY

- Additional parameters are needed to account for energy degradation in air

$$D_{\text{air}} = f(D_{\text{vac}}, \mu_e(r, E)),$$

where  $\mu_e(r, E)$  is a function that accurately describes the impact that air has on electron dosimetry.

- Generally, one could write  $D_{\text{air}} = D_{\text{vac}} \exp(-hr)$ , where  $h$  behaves similarly to  $\mu$  for photons. This formulation fails for purposes of this analysis, though, for three reasons.
  - The analysis concerns distances in air up to 10 m
  - The size and shape of the target volume play a significant role in electron dosimetry
  - Bremsstrahlung generated in air is a key component of electron dose

# ELECTRON DOSIMETRY

- While traversing through space, the electron fluence undergoes dramatic transformations that are not adequately described by simple exponential decay

- An empirical expression accounting for the effects of air was derived:

$$D_{\text{air}} = \frac{B^-(q, s)}{ar^2 + br + c\sqrt{r} + d} + \frac{B^+(q, s) B^-(m, n)}{tr^2 + ur + v} + \frac{k B^+(1000, z)}{(1 + r)^j}$$

## PROTECTIVE GLASSES

- Incorporating shielding for electrons requires a slight modification of the unshielded  $D_{\text{air}}$  equation and recalculation of each of the shaping parameters
- Similarly, the shielded electron dose model is:

$$D_{\text{sh}} = \left[ \frac{\mathcal{B}^-(q, s)}{ar^2 + br + c\sqrt{r} + d} + \frac{\mathcal{B}^+(q, s) \mathcal{B}^-(m, n)}{tr^2 + ur + v} + \frac{k \mathcal{B}^+(1000, z)}{(1 + r)^j} \right] [\mathcal{B}^-(y, 0)].$$

## TOTAL DOSE

- In the presence of discrete energy particles (such as Auger electrons, characteristic x-rays or gamma rays) and continuous energy spectra (such as beta radiation or x-ray machines), total dose is given by:

$$\begin{aligned}
 \dot{D}_{\text{total}} = & \sum_{\text{discrete photons}} A_i D_p(E) \\
 & + \sum_{\text{continuous photons}} A_i \int_E D_p(E) \cdot P_i(E) dE \\
 & + \sum_{\text{discrete electrons}} A_i D_e(E) \\
 & + \sum_{\text{continuous electrons}} A_i \int_E D_e(E) \cdot P_i(E) dE .
 \end{aligned}$$

# VERIFICATION AND VALIDATION

# VERIFICATION AND VALIDATION

# COMPARISON TO VARSKIN

# COMPARISON TO VARSKIN

# CURRENT LIMITATIONS

- Cannot adjust eye glasses parameters – built directly into the model
- Assumes eyeball being irradiated is staring directly at the source for the entire exposure
  - Sensitivity study shows dependency on off-axis angle and energy
  - The difference between the on-axis and off-axis dose might be within 20 percent provided that  $\theta < 20^\circ$
